BARBERRY ERADICATION IN 1931

Summarized Results Covering the Period 1918-1931.

By F. C. Meier, Principal Pathologist, in Charge and

W. L. Popham, Senior Pathologist, Division of Barberry Eradication.

INTRODUCTION

In the thirteen years during which the barberry eradication campaign has been in progress, approximately eighteen and one-half million rust susceptible bushes have been destroyed in the thirteen North-Central and Western grain-growing States comprising the area. That the eradication of these bushes has resulted in a decided decrease in rust losses is indicated by the fact that during the five-year period, 1916-1920, the average annual loss from stem rust was estimated at 57,000,000 bushels, while for the five-year period, 1926-1930, it was less than 10,000,000 bushels annually.

The cradication of the remaining barberry bushes should further reduce the severity, if not eliminate destructive epidemics of stem rust in the upper Mississippi River Valley. Furthermore, it will retard hybridization of physiologic forms of stem rust which takes place on the barberry leaves resulting in new forms of the fungus capable of attacking varieties of small grain that have previously proven resistant. As a result of past work, the remaining common barberry bushes are few and scattered in some States, while in others, such as Iowa, Wisconsin, Ohio, Illinois, and Michigan, there are many localities in which thousands remain.

The losses that continue to occur can be attributed to two causes: (1) The spread of rust from remaining barberry bushes, and (2) The development of rust in certain years as a result of spores carried by the wind from the Southern States where the red or repeating stage of the disease lives over the winter. Epidemiology studies made since the beginning of the barberry eradication campaign in 1918 have shown that in the

Northern States the early development of stem rust and the most demaging epidemics of the disease are associated with the remaining common barberry bushes. However, during certain seasons when an abundance of rust is present in the South and wind, moisture and temperature conditions favor the northward movement of spores, stem rust may develop in the spring-wheat area as the result of wind-blown ineculum. Rust from this source usually appears later in the growing season and is characterized by a scattered distribution over extensive areas. Unless crops are abnormally slow maturing, serious rust damage ordinarily does not occur.

trating on attempts (1) to reduce the expense of finding the remaining barberries in those areas in which they are somewhat scattered, and (2) to reduce the cest of cradication in areas in which the bushes are numerous, particularly where they have escaped from cultivation. Progress is being made in developing the initiative of property owners and children with the result that more individuals each year become interested in stem rust control, learn to recognize the common barberry, and realize the necessity for cradicating it.

The cormon or European barberry, although not native to the United States, was widely distributed over the country for ornamental and hedge purposes. From the original plantings it has sproad rapidly as the result of birds and other agencies scattering seed to timber lands, stream banks, fonce rows and other uncultivated lands. Until some concrote evidence could be produced that the climination of this more or less decorative shrub would have a limiting effect upon the destructiveness of stem rust, support of individual property owners in many parts of the area was noticeably lacking. The result of concentrated eradication efforts in some of the more important grain areas has provided a thorough test for recommended control measures and proven the practicability of the work. This is shown by the experiences of many individual farmers who have had little, if any difficulty with rust since barborry bushes in the vicinity of their farms have been eradicated and by the decided reduction in stem rust losses that has come about in the spring-wheat area during the past ten years.

THE DEVELOPMENT OF THE BARBERRY ERADICATION PROGRAM

The interest of proporty owners in the prevention of stem rust has been increasing rapidly since the climination of millions of rust-spreading bushes during the early years of the campaign and the establishment of the practicability of barborry eradication as a control measure. In States where the remaining common barberry bushes are few, the farm-to-farm survey method of conducting the program is being replaced with increased efforts along informational lines and detailed seasonal study of rust conditions. The object is to make available to the public information which Will enable individuals to actively participate in ridding their own communities of rust-spreading bushes and through study of the rust situation each year to accumulate information regarding localities where the prevalence and the severity of the disease indicates the probable locations of inoculum centors.

In an attempt foward further increasing the effectiveness of the field program during 1931, efforts of locally employed cradication forces were concentrated in areas where barberry bushes are numerous and so situated as to be a continued menace to small grain growers. A proportionally larger number of local people were employed for eradication work in localities where bushes were numerous. The field season was extended in order to obtain a longer period of service for fewer temporary agents selected for their ability to organize eradication crews and develop the informational phase of the campaign. Further attention was given to improving the Quarantine regulations and making more effective contacts with nurserymen to obtain their cooperation in preventing the introduction of susceptible barberry bushes into the principal small grain-producing States. The strictest economy was followed in the administration of travel and other operating expenses.

THE ADMINISTRATION OF BARBERRY ERADICATION DURING 1931.

Organization. The barberry eradication campaign was organized in 1918 under the direction of the Bureau of Plant Industry, United States Department of Agriculture, with the agreement that the program was to be developed jointly with the following thirteen States: Colorado, Illinois, Indiana, Iowa, Michigan, Minnesota, Montana, Nebraska, North Dakota, Ohio, South Dakota, Wisconsin and Wyoming. During the early years of the campaign an agent of the Department of Agriculture was retained in each of the States to supervise and conduct informational activities, survey and eradication, and a limited amount of research. As the campaign progressed and barberry bushes became less numerous in some of the Western States, three District offices were created at Fort Collins, Colorado; Brookings, South Dako ta; and Fargo, North Dakota, to continue the work in the Western States, including, in addition to those named above, Nebraska, Wyoming and Montana. Leaders in charge of the ten field offices conducted their work in cooperation with State Colleges and State Departments of Agriculture.

Cooperation. Organizations cooperating with the Division of Barberry Eradication, Bureau of Plant Industry, United States Department of Agriculture, in conducting the barberry eradication campaign are State Colleges of Agriculture, State Departments of Agriculture and many independent agricultural and business organizations within the thirteen States. The Conference for the Prevention of Grain Rust, Minneapolis, Minnesota, an organization of agricultural and business leaders in the eradication area, has, from the beginning, taken an active interest in the campaign and each year furnished liberal financial support in developing the informational side of the program. The Farm Bureau and Grange also have actively supported the work. In the center of the hard red spring-wheat area the North Dakota Retail Merchants Association and Greater North Dakota Association have actively participated in the program.

Finance. Barberry eradication is financed largely through Federal appropriation. Many of the States have made direct cash appropriations and all have given indirect financial aid in service and equipment. The Federal money available for expenditure during the fiscal year ending June, 1932, was approximately \$300,000. The total direct and indirect aid furnished by States for the same period was \$87,540.

THE PROGRESS : NDE IN BARBERRY ERADICATION DURING 1931.

The activities of the barberry cradication campaign may be classified under three headings: Survey and cradication, Informational Activities, and Investigations. A brief report of the results in each of these fields of activity follows:

SURVEY AND ERADICATION. Territory in which cradication efforts were concentrated during the past year was selected after careful consideration had been given to the requests for assistance in stem rust control received from county agents and individual grain growers. Rust data accumulated during past years were reviewed in an attempt to determine localized areas in which damaging epidemics of stem rust recurred at frequent intervals. The final selection of counties or parts of counties to be given attention was made by the resident leader in charge after discussing needs and opportunities with State cooperators and Washington officials. The final plan for procedure was approved by the Principal Pathologist in Charge of the Division.

Although many barberry bushes remain scattered throughout the thirteen States, by concentrating efforts of eradication during past years in localities where bushes were more likely to produce destructive epidemics of rust, it has been possible to greatly decrease losses from this source.

During 1931 common barberries were found on 1,717 properties. More than 171,000 bushes were destroyed. The total number of bushes located and destroyed during the past year is much less than in some previous years. One of the principal reasons for this difference is that within the western part of the barberry eradication area the campaign has progressed to the point where remaining bushes are much less numerous than they were a few years ago. It is important, however, that all common barberries be destroyed to insure future protection from rust and to prevent the remaining bushes from resceding extensive areas.

Applying crushed rock salt to the crown of barberry bushes continues to be the most popular, economical and efficient method of eradication. Bushes properly treated with salt will never sprout; consequently, digging or grubbing is resorted to only when the application of crushed rock salt would prove injurious to other shrubbery or trees. During the season approximately 195 tons of salt were used.

INFORMATIONAL ACTIVITIES. A costly part of the barberry eradication campaign is to locate bushes that have developed from seeds scattered by birds. If the desired progress is to be made it is necessary for grain grovers and those residing in grain-producing areas to become more generally informed regarding the common barberry and its specific relation to the dissemination of stem rust. During the past year considerable revision was made in plans for continuing the barberry cradication program. A substantial reduction in the amount of Foderal funds available made decided curtailment in field activity mecessary. In keeping with the policy to encourage individual property owners to assume more of the responsibility for clearing their own farms and communities of barberry bushes, purely service work was retarded in order that more time and attention could be given to the informational side of the program. Although the more intensive type of informational work is being met with a public response beyond expectations, the continuance of a certain amount of service work must remain an important part of the program in order to insure the cradication of barberry bushes growing on public lands, in cities and towns, and in non-agricultural communities, as well as in the vicinity of grain fields.

Interest of Property Owners Increasing. The fact that property owners are ready to take an active part in stem rust control has been clearly demonstrated time and again in the experience of field agents. It is apparent, however, that satisfactory completion of the work will require that the Department of Agriculture and cooperating agencies provide local leadership to insure a thorough search for the bushes and to supervise cradication. In many localities where barberry bushes are found numerous a careful survey by agents of the Department undoubtedly will prove necessary.

The practical development of the informational phase of the barberry eradication campaign requires a well-organized extension program, local contact and leadership, and the judicious distribution of printed information setting forth in popular form the cause, effect, and recommended means of controlling stem rust.

Individual Project Reports. Detailed reports covering individual projects in each of the thirteen States are on file in the Division of Barberry Eradication. The general informational program includes demonstrations at fairs and other public gatherings, joint meetings with county agents and other agricultural workers, assistance with instruction in general science and agricultural classes in rural and city schools and numerous projects with juvenile organizations such as Future Farmers of America and 4-H Clubs.

Printed information and illustrative laboratory materials pertaining to the control of stem rust and other diseases of economic crops have been used, during the past two years, in general science and agricultural classes in public schools of the spring wheat-growing States attended by more than 100,000 pupils. Some indication of the resulting value to the campaign is suggested in the fact that more than 400 pupils have reported the location of barberry bushes. As a direct result of these reports more than 7,000 bushes have been destroyed.

In Sioux Falls, South Dakota, the high school biology instructor is making extensive use of materials pertaining to the centrel of stem rust in his science classes. As a follow-up to classroom instruction he is directing his students in a shrubbery survey of the city and has offered the assistance of the school in recording the location of remaining barberry bushes. His method of developing a practical objective for his classroom work is being adopted in many other South Dakota schools. The voluntary service to be received from these groups will materially hasten the completion of the program in that State.

Another outstanding example of group cooperation is recorded in the cooperative project being conducted with weed inspectors in approximately twenty counties in Minnesota. In southwestern Minnesota, farmers have organized, with the help of county agents, in an attempt to more effectively combat weeds. Under the plan one man on each section of ground is designated as local weed inspector. These people make regular inspections of the farms in their communities to see that weeds are not allowed to produce seed. The same consideration is being given to the eradication of common barberry as to other noxious weeds in these counties.

The identification of the common barberry is being emphasized in the informational work. As more people learn to recognize it, additional responsibility will be removed from the Federal and State agencies in connection with eradication activities.

Preparation of Materials. In the preparation of illustrated materials and printed matter to be used in connection with the informational work, an attempt is being made to fit the materials to the particular program being developed. During the past year the Conference for the Prevention of Grain Rust in Minneapolis has made possible the preparation of a set of lecture charts depicting the life history of the black stem rust, and, accepted methods for controlling the disease. These charts are being used extensively by agents when talking before groups of adults or children.

Miscellaneous Publication #131 shows in colors the characteristics of the common barberry bush, the development of stem rust from early spring until late fall and the effect stem rust has upon the wheat crop. The publication includes a brief summary of the principal facts concerning barberry eradication and provides an economical piece of literature for distribution to those interested in small grain production.

A lesson plan and materials suitable for laboratory instruction have been made available for teachers in rural and city schools. As previously stated, this material is being used extensively and has been found by State Department of Education officials valuable as supplementary information for teachers to use in general science and agricultural courses.

In addition to the above materials, leaders in each of the States have made restricted use of form letters, brief progress reports and magazine and newspaper articles.

INVESTIGATIONS. The development and spread of cereal rusts in the small grain areas extending from Moxico through the Mississippi River Valley to the Canadian border is studied each year to further add to accumulated information regarding different sources of inoculum and to determine, in so far as possible, the rapidity and extent of migration of stem rust spores. By determining each year the physiologic forms of the rust present on grain stems in widely separated localities it is possible to obtain some indication as to whether primary infection has resulted from spores disseminated from local barborry bushes, or, spores carried by the wind from distant localities. The physiologic form study and other field observations are supplemented with data collected from slides exposed from buildings and airplanes at various points throughout the Mississippi River Valley. The number and kind of rust spores caught on vasclined microscope slides, taking into censideration wind direction and other climatic factors, gives some indication of the spore content of the air and probable extent and rapidity of the movement of inoculum.

There are many forms of stem rust and each reacts differently toward individual host plants. For example, there is one which causes rust on oats but not on wheat, barley or ryo. Another causes rust on wheat and barley and to a limited extent on ryc but not on oats. Still another causes rust on rye and barley but not on wheat and oats. Others cause rust on timothy but not to any extent on any of the cereals. Some rust blue grass but do not attack any of the small grains. These varieties or forms of rust have been given a number in order that one may be distinguished from another. Grain may be heavily rusted near barberry bushes one year and the grain near them comparatively free from the disease the next year, although the bushes again may be badly rusted. The reason is that the kind of grain near the barberry bushes may not be susceptible to the form of rust present.

Physiologic Form Suvey. As a result of the physiologic form survey, sixtoen different forms were found when 552 identifications of rust on wheat stems were made. Five of these were widely distributed as in 1929-30 and they crollisted in the order of their prevalence: Forms 36,49,38,11 and 21. All five forms were provalent in Texas and Forms 38 and 49 were common in Mexico. The number of specimens containing Form 49 diminished rapidly as the rust survey progressed northward. On the other hand, the prevalence of Form 36 increased.

More than 300 collections of oat stem rust were identified consisting of either Form 2 or 5. Form 2 was the most prevalent. Both, however, occurred in all States from which three or more collections were received.

From aecial collections, seven forms were isolated, two of them for the first time. The other five were the same as those identified from wheat collections. Forms 38 and 49 were isolated most frequently from the aecial (raterial instead of 36 and 49 as in the case of wheat collections. Since only a comparatively few barberry specimens were collected, too much importance cannot be attached to these figures.

Epidemiology. During 1931 a heavy epidemic of stem rust developed in most fields of grain in central and northern Mexico. Stem rust over-wintered in a small percentage of the fields of wheat in the central and northern parts of Texas and on oats in the southern and central parts. However, during the season the disease developed slowly and the north-ward migration occurred only in short waves. Field observations indicate that inoculum from the south arrived in the spring-wheat area a few days later in 1931 than in the average year.

Nursery Inspection. As a part of the cooperative work with nurserymen, extensive tests are being conducted to determine the relative susceptibility to stem rust of many varieties of barberry developed or introduced in recent years. A handbook, containing information including drawings of the more commonly grown varieties, has been prepared as a reference for Quarantine inspectors and others to use in making identifications. Provision is made for inspecting nurseries where barberry bushes are offered for sale in keeping with the requirements of Quarantine (38 Revised) governing distribution of these bushes.

Susceptibility Studies. In 193 series consisting of from three to six plants each, 41 species and varieties of barberry were inoculated with stem rust. In each series one or more plants of species or varieties known to be susceptible were used as checks. Telia of five varietie of stem rust provided the inoculum although the Secalis variety was the one most commonly used. Most of the varieties of barberry tested recently have proven resistant or immune. The study of susceptibility of different varieties is being developed as rapidly as possible in order to classify all species of Berberis either as susceptible, resistant, or immune to stem rust.

Other stem rust studies directly related to the control program being conducted in this Division include overwintering of uredinityspores in the north, development and spread of stem rust in the vicinity of barberry bushes and the occurrence and distribution of stem rust in the spring-wheat area.

Chemical Investigations. Research on chemical methods of cradication begun in 1930 as a cooperative project with the Division of Blister Rust Control was continued with a study of bushes treated at Maumee, Ohio, in 1930 and the establishment of new test plets at Pennsylvania Furance, Pennsylvania. Some of the new chemicals have given such promising results that it is planned to make more extensive trials of them in areas of escaped bushes in Illinois, Wisconsin, Colorado and Minnesota. In the meantime, the use of salt, which has proven an effective killing agent, will be continued although it is heavy to handle in large amounts.

FUTURE PLANS FOR BARBERRY ERADICATION

In outlining the most effective type of field program for the 1932 field season, taking into consideration probable appropriations for continuing the work, a careful analysis of the present state of progress in barberry eradication has been made with regard to locations where bushes are known to exist and communities where the severity of stem rust indicates possible sources of local infection. Conditions vary widely in different parts of the area but for administrative purposes the territory included in the barberry eradication area may conveniently be divided into four classes:

In Class I most of the land is either cultivated or occupied by well-kept pastures or woodlots. The area includes most of Ohio, Indiana, Iowa, southern Michigan and parts of Wisconsin, Minnesota, South Daketa and Nebraska. In these States intensive farming methods are practised. Many barberry bushes have been planted and many have escaped cultivation. Survey involves centinued contact with property owners and a large pertion of the time is spont in finding and killing barberries in orchards, gardens and woodlots in

the immediate vicinity of farm buildings. An extreme example is Montgomery County in Ohio where one or more barberry bushes were found on practically every square mile of territory in the county. Most of these were bushes that had grown from seeds scattered by birds and other agencies.

In Class II most of the area is made up of rough woodland, creeks, rivers and pastures. It includes large areas in Wisconsin, parts of Ohio, Michigan, Illinois, Iowa, and Minnesota. In Wisconsin and certain parts of the other States named the most extensive problem is that of conducting eradication activities in large areas of escaped bushes. This requires a careful survey or inspection of timbered land, creek bottoms and pastures. In addition, there are numerous more or less extensive areas of escaped bushes in Indiana and eastern Nebraska.

In Class III most of the area is open plains and prairies with relatively little native or planted shrubbery. Most of North Dakota, South Dakota, eastern Montana, western Nebraska, eastern Colorado, eastern Wyoming, westorn Minnesota and southern Illinois, is included in this class. In the Dakotas there is a very distinct type of territory to be covered. Natural vegetation is less plentiful then in States farther east. Fewer barberries were planted and climatic conditions are such that they have not increased rapidly in number. The problem here is to carefully search city and rural properties that have been planted with shrubbery and where barberry bushes are found to intensively scout the adjacent woodlots, river banks and stream beds for possible escapes. A single barberry bush in this area where hard spring-wheat is the major cash crop may cause an enormous amount of damage in a single season, providing weather conditions favor the development of rust.

Most of the area in Class IV is made up of hillsides and mountain-sides that are either heavily timbered or covered with dense brush. This type includes the western part of Colorado, Montana and

Wyoming, and some territory adjacent to the Mississippi and other large rivers. The amount of territory in this division is not so extensive as that in each of the other three. However, in order to successfully complete the cradication program, prevent reinfestation of areas now free from bushes and provide local insurance from stem rust epidemics, it is believed important to continue cradication offorts in these areas.

PROPOSED PLANS FOR CONTINUING BARBERRY ERADICATION

In proposing tentative plans for procedure for the coming field season consideration has been given to the probable Federal and State appropriations for this work. The allotment of funds to field offices has been carefully studied in an attempt to balance the amount of informational and survey work authorized in the different States with the urgency of needs. Some revision of field methods is planned so as to most effectively utilize the limited funds available. Administrative and routine expenditures will be reduced to a minimum both in the Washington office and in the field.

A general policy for procedure throughout the area based upon the different classes of territory described above involves:

- (1) The use of local labor for survey work in areas of escaped bushes or in territory where extensive pastures or timber lands must be carefully inspected.
- (2) The employment of fewer and better qualified men during longer periods of time for continuing the informational and contact work.
- (3) Collecting of detailed information regarding occurrence and distribution of stem rust in the more inportant small grain districts as an aid to determining where available funds may be most effectively utilized.
- (4) The development of more voluntary activity on the part of property owners and children in the eradication of known bushes.

For territory included in Class I which is typical of large areas in Ohio, the following procedure, subject to local variations, will serve as a guide in developing a satisfactory program.

One man with experience and training will be employed to organize the barberry program in a limited area comprising one or two counties or parts of counties depending upon local conditions. His efforts will be concentrated in an attempt to induce local adults and children to look for and report barberry bushes. If an extensive eradication program develops, local labor will be employed to assist property owners in cradication. Where the regular farm-to-farm survey is continued, the trained man can make the contacts in the community and employ local labor to promptly complete the intensive survey and oradication work. The responsibilities of the men placed in charge of local activity will include a knowledge of the rust situation in his District. This may be obtained through persona observations and through data furnished him by members of the Future Farmers of America or similar organizations whose cooperation has previously been arranged.

Class It territory requires the maintenance of an effective and economical eradication organization. In States such as Wisconsin, numerous areas of common barberry are located where the cradication problem is too extensive to be handled by individuals in the community. Under such conditions it is proposed to employ local cradication crews which will be supervised by a trained agent capable of making the necessary contacts and conducting other phases pertaining to the informational side of the work. Eradication of large areas of escaped bushes does not progress rapidly and territory to be given immediate attention will be selected on the basis of the proximity of bushes to grain fields, past history of stom rust in the community, and the probability of future spread of barberry bushes from seed. In those areas requiring prolonged intensive work the value of informational activities will net be overlooked. Bushes will reappear in the future and a well-informed public will greatly assist in retarding the rapid spread which has heretofore occurred.

Territory in North Dakota is more or less representative of that included in Class III. The problem of eradication becomes quite distinct from those discussed above. Although locations of barberry bushes are few and widely scattered, those remaining are important from the economic point of view and should be cradicated as promptly as possible. A practical program for locating these bushes undoubtedly will require a highly effective informational organization. Intensive scouting which was necessary in the early part of the campaign is too expensive a method for locating the remaining bushes. In North Dakota and States containing similar type of territory, the combination of a carefully organized informational program and an intensive rust survey should indicate the possible sources of rust infection and provide a sound basis on which to proceed with future control offorts. It is believed one man skilled in extension methods and with previous experience in barberry eradication could develop a program in an area comprising not more than two counties which would lead to the location of a large percentage of the remaining bushes. For this reason specific attention is being given to the selection of temporary agents who will continue the field work in this class of territory. It is intended that these men should be employed for a period of eight or nine months each season and during this time confine their efforts to restricted areas. By taking advantage of informational opportunities and encouraging grain growers to report either badly rusted grain fields or known locations of barberry bushes the agent in charge of local activity should be able to locate many of the remaining bushes by the close of the field season. In Class III territory the future cradication problems will not prove difficult. Where areas of escaped bushes are located it is believed that oradication . activities can be handled with local assistance as suggested for Classes I and II.

Class IV territory, although quite different with respect to location, natural vegetation, and relation to the general rust situation, hardly requires a separate discussion. Where extensive areas of bushes are found it is probable the situation can most economically be cared for with local labor as suggested in Classes I and II. Escaped barberry bushes in dense undergrowth, along rivers and adjacent to mountains present a difficult problem. If suitable local assistance can be obtained for conducting this type of survey, the cost will be greatly reduced.

The following forms and maps provide a detailed statistical record of the progress made in barberry cradication since the beginning of the campaign in 1918.

First Survey, Properties, January 1 to December 31, 1931.

Data showing, by States, the number of properties on which barberry bushes were found and destroyed in all surveys, and the number of properties upon which seedlings were found and destroyed in the first and second surveys in the calendar year January 1 to December 31, 1931. Table 1.
